Abstract

The Casimir effect is attractive in most vacuum-separated metallic or dielectric geometries. Two electrically neutral spatially separated systems interacting via Casimir force will have access to the stable separation state only when the force transitions from repulsive at small separations to attractive at large separations. Such issues are important in the future development of micro- and nano-electromechanical systems (MEMS and NEMS). We investigate here the Casimir-Polder free energy corresponding to interactions of a magnetically and electrically polarizable micro-particle with a magneto-dielectric sheet. Our theoretical study shows that such an interaction is tunable in strength and sign. The latter, particularly, is true provided we go beyond the natural materials and look for the meta-materials fabricated at scales between the micron and the nanometer. We assume that the particle and the sheet have access to non-trivial values of the polarizability ratio and the electromagnetic impedance, respectively. The crossover between attractive and repulsive behavior is found to depend on these quantities.

Keywords: Casimir effect, Vacuum-separated metallic geometry, MEMS and NEMS, Casimir-Polder free energy, Magneto-dielectric sheet, Non trivial magnetic susceptibility, Electromagnetic impedance.

The mutual electromagnetic correlation between two spatially separated systems gives rise to Casimir/ Casimir-Polder effect. The corresponding forces, which are generally attractive for most vacuum-separated metallic or dielectric geometries, are due to the contribution to the ground-state [1,2] energy of the coupled system. The repulsive Casimir forces [3] are believed to occur in four types of materials, viz. the fluid-separated dielectrics [4], the composite meta-materials [5], the systems with different geometries [6,7], and the time-reversal symmetry (TRS) broken systems [8,9]. It is well-known [10,11,12] that the Weyl semimetal state—a novel topological phase of matter—must break TRS or the inversion symmetry. Therefore, the corresponding host materials are expected to yield a Casimir/Casimir-Polder (CP) repulsion tunable with carrier doping or a magnetic field [13]. Experimentally, the forces have been realized for the first time involving test bodies immersed in a liquid medium-ethanol [4]. We investigate here the Casimir-Polder free energy corresponding to interactions of an electrically and magnetically polarizable micro-particle with a magneto-dielectric sheet. Our task is to look for the repulsive Casimir-Polder forces between a micro-particle possessing non trivial ratio of the magnetic polarizability and the electric polarizability and the artificially engineered dielectric material (meta-material) sheet having non trivial magnetic permeability values, as the natural materials have a magnetic permeability roughly equal to one in the range of frequencies relevant for the Casimir effect. The natural materials, such as ferrites and garnets, are perhaps suitable to demonstrate the repulsive Casimir force as they have high permeability. We show that for non-trivial permeability values, the crossover between attractive and repulsive behavior depends on ‘polarizability ratio’ of the micro-particle, and the impedance Z = √(μ/ε) of the sheet apart from the ratio of the film thickness and the micro-particle separation (D/d) and temperature(T). The importance of CP repulsion cannot be understated. The repulsion stabilizes the operation of MEMS and NEMS, as it liberates one from the badgering problem of ‘stiction’ in such systems.

We consider a micro-particle in an intervening medium characterized by the dynamic electric polarizability η(ω) and the dynamic magnetic polarizability η(ω) as shown in Figure 1. The static electric and magnetic polarizabilities of the micro-particle are η(0) and η(0), respectively. We wish to discuss first the Casimir-Polder interaction in the static limit. We define their ratio as r(0) = η(0)/η(0). The quantities ε(0)(ω) and μ(0)(ω) are the dynamic dielectric permittivity and the dynamic magnetic permeability of the intervening medium. If the medium happens to be vacuum and then each of them is equal to one. The sample in the figure consists of a thin magneto-dielectric film of thickness D deposited on a thick substrate at temperature T. Suppose the film is characterized by the dynamic electric polarizability η(ω) and the dynamic magnetic polarizability η(ω) as shown in Figure 1. The static electric and magnetic polarizabilities of the micro-particle are η(0) and η(0), respectively. We wish to discuss first the Casimir-Polder interaction in the static limit. We define their ratio as r(0) = η(0)/η(0). The quantities ε(0)(ω) and μ(0)(ω) are the dynamic dielectric permittivity and the dynamic magnetic permeability of the intervening medium.
might be made of either conducting or poorly conducting materials. Also, for the film material there exist finite limiting values \(\varepsilon^{(1)}(0) \equiv \varepsilon^{(1)}(0)\) and \(\mu^{(2)}(0) \equiv \mu^{(2)}(0)\). The finite limiting values of these quantities for the substrate are \(\varepsilon^{(2)}(\omega)\) and \(\mu^{(1)}(\omega)\). These static values are the values of the Faraday-Maxwell dielectric constant and permeability. For the fields slowly varying in space and time, such limiting values of the function \(\varepsilon^{(1)}(\omega)\) and \(\mu^{(2)}(\omega)\) exist. Our first aim is to investigate the interaction of the micro-particle with the magneto-dielectric sheet in this limit, ignoring the frequency dependence completely. Suppose now the particle is at a separation \(d \gg d(T)\) above the sample. We assume the interaction of the particle with the sheet to be a first approximation. The classical Casimir-Polder type (CPI) interaction originates from the characteristic fluctuations on the sheet material plus substrate, dependent on the wave vector projection \(k\) on the \((x,y)\) plane and also on the frequency, for two independent modes, viz. the transverse magnetic (TM) and the transverse electric (TE) polarizations,by \((i\omega, k)\), and \((i\omega', k')\), respectively. Here \(\omega = (2\pi l k_B T)/\hbar\) are (imaginary) Matsubara frequencies. The dependence on \(\omega\) is borne out by the fact that the Casimir/ Casimir-Polder force not only arises from the fluctuations of the electromagnetic field, which are purely quantum-mechanical objects, they also have a thermal contribution [1,18] at nonzero temperatures. The closed-form, precise expressions for these reflection coefficients, including the thermal contribution, are given by the Fresnel coefficients \((i\omega, k)\) and \((i\omega', k')\) ((15,16,17)) (the Fresnel coefficients are calculated along the imaginary axis ((15,16,17)) corresponding to the reflection on the boundary planes between the vacuum and the film material \((n = 0, n' = 1)\) and also between the film material and the substrate \((n=1, n' = 2)\):

\[
\Pi_\beta = \frac{d_R^{(1)}(\omega, k) + d_T^{(1)}(\omega, k)}{d_R^{(1)}(\omega, k) - d_T^{(1)}(\omega, k)} \approx \tan\left(\frac{\pi}{4} - \frac{i\omega}{k_B T}\right).
\]

Here, the indices \(\alpha, \beta = (m, e)\) denote the transverse magnetic (TM) and the transverse electric (TE) modes. The Fresnel coefficients, which describe the reflection and transmission of electromagnetic waves at an interface, are given by

\[
\begin{align*}
\frac{d_R^{(1)}(\omega, k) + d_T^{(1)}(\omega, k)}{d_R^{(1)}(\omega, k) - d_T^{(1)}(\omega, k)} &\approx \tan\left(\frac{\pi}{4} - (i\omega, k)\right),
\end{align*}
\]
\[ \mathcal{S}_e(i\omega, k^\text{\tiny +}) = \frac{\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny +})}{[\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny -})]^{1/2}} = \tan^{-1}(\pi/4 - (i\omega, k^\text{\tiny +})), \]  

(3)

where

\[ (i\omega, k^\text{\tiny +}) = \arctan(\varepsilon(n)(i\omega, k^\text{\tiny -})), \]  

(4)

\[ (i\omega, k^\text{\tiny -}) = \arctan(\mu(n)(i\omega, k^\text{\tiny -})), \]  

(5)

\[ k(n)(i\omega, k^\text{\tiny -}) = \sqrt{k^\text{\tiny +}^2 + \varepsilon(n)(i\omega, k^\text{\tiny -})\mu(n)(i\omega, k^\text{\tiny -})/(\omega^2/c^2)}. \]  

(6)

The reflection coefficients \((i\omega, k^\text{\tiny +})\) of the electromagnetic fluctuations on the sheet material plus substrate in view of Eqs. (2)-(5), for the transverse magnetic (TM) polarization, could be written as

\[ \Pi_m(n=0 \rightarrow n^\prime = 1, n=1 \rightarrow n^\prime = 2) \begin{bmatrix} (i\omega, k^\prime) \rightarrow k/2d \end{bmatrix} = \frac{\tan^{-1}(\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny +})) + \tan^{-1}(\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny -}))}{\tan^{-1}(\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny +})) + \tan^{-1}(\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny -}))}. \]  

(7)

where we have introduced a dimensionless variable in place of \(k^\text{\tiny +}\) above, viz. \(k = 2d k^\text{\tiny +}\). In view of Eqs. (7) and (8), one obtains the simple expression for the Casimir-Polder free energy density as

\[ F(d) = -\left(\frac{\pi^2 N^2}{48\hbar^2}\right) \sum_{n=0}^{\infty} \int_o^{\infty} k^2 dk \cot(k^\prime) \eta_s(i\omega, \eta_s(i\omega)) \]  

(9)

The dielectric constant \(\varepsilon^{\text{\tiny +}}(i\omega, \eta_s(i\omega))\), the electric polarizability \(\eta_s(i\omega, \eta_s(i\omega))\), etc. though written as function of frequency above, in general, is a function of frequency and the wavevector both. They describe the response of a medium to any field. As already mentioned, for the fields slowly varying in space and time, the limiting value of these functions are the Faraday-Maxwell dielectric constant and the static electric polarizability \(\eta_s(0)\). We shall assume the magnetic polarizability of the micro-particle and the permeability of the sheet material having the similar limiting static values below.

The important outcome, of the Faraday-Maxwell (static) limit, is that \(k^{\text{\tiny +}}(i\omega, k^\text{\tiny +}) = k\). In view of (2) and (3) one is then able to write

\[ \mathcal{S}_m(n=0 \rightarrow n^\prime = 1, n=1 \rightarrow n^\prime = 2) \begin{bmatrix} (i\omega, k^\prime) \rightarrow k, \eta_s \end{bmatrix} = \frac{\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny +})}{[\varepsilon^{\text{\tiny +}}(i\omega, k^\text{\tiny -})]^{1/2}} = \tan^{-1}(\pi/4 - (i\omega, k^\text{\tiny +})), \]  

(10)

The summation \(\Sigma\) in (9) disappears in this static limit. It must be clarified that this limit is not the same as the low-temperature limit where \(\omega_s\)’s will get closer to each other and at zero temperature all of them contribute to dissipation. Thus, the Casimir-Polder free energy assumes the simpler form

\[ F(T, \ldots) = \frac{1}{\hbar^2} \sum_{n=0}^{\infty} \int_0^{\infty} k^2 dk e^{-\kappa} \eta_s(0) \eta_p(n \rightarrow n^\prime = 1, n=1 \rightarrow n^\prime = 2) \]  

(11)

where

\[ \Pi_m(n=0 \rightarrow n^\prime = 1, n=1 \rightarrow n^\prime = 2) = \frac{\eta_s(0) \eta_p(0 \rightarrow 1)}{\eta_p(0 \rightarrow 1)} \]  

(12)

\[ \Pi_p(n=0 \rightarrow n^\prime = 1, n=1 \rightarrow n^\prime = 2) = \frac{\eta_s(0) \eta_p(0 \rightarrow 1)}{\eta_p(0 \rightarrow 1)} \]  

(13)

This is the formal expression of the Casimir-Polder force corresponding to interactions of an electrically and magnetically polarizable microparticle with a magneto-dielectric sheet. Here the impedance of the sheet is \(Z(1) = \sqrt{\mu(1)/\varepsilon(1)}\), where \((\mu(1), \varepsilon(1))\) are the magnetic permeability and the dielectric permittivity of the film material, respectively. Similarly, the polarizability ratio of the micro-particle in vacuum is \(r(0) = \sqrt{\eta_m(0)/\eta_e(0)}\), where \(\eta_m(0)\) and \(\eta_e(0)\), respectively, are the static magnetic and the electric polarizability of the micro-particle in vacuum. Note that the Casimir/ Casimir-Polder force arises from fluctuations of the electromagnetic field which are purely quantum-mechanical objects. At nonzero temperatures, the fluctuations also have a thermal contribution [1,18]. In our approximation of ignoring the frequency dependence completely, a significant physical information is lost: The formula (9) is written in terms of the imaginary frequencies though it has a representation in the real frequency domain as well [19,20]. The latter enables one to analyze the contributions from propagating and evanescent waves separately. At small distance the repulsive evanescent contributions are found to be dominating for the transverse electric polarization in the case of metallic objects [20]. Therefore, the thermal contributions need to be taken into account to discuss the Casimir-Polder repulsion. Furthermore, if the film happens to be isolated, then \(\varepsilon(2)(0)\) and \(\mu(2)(0) = 1\). All these restrictions enable us to write

\[ \mathcal{S}_m(n=0 \rightarrow n^\prime = 1, n=1 \rightarrow n^\prime = 2) = \frac{\varepsilon^{\text{\tiny +}}(0, k^\text{\tiny +})}{[\varepsilon^{\text{\tiny +}}(0, k^\text{\tiny -})]^{1/2}} = \tan^{-1}(\pi/4 - (0, k^\text{\tiny +})), \]  

(10)

We can obtain, in principle, the Casimir-Polder energy by evaluating the integral (11) considering the terms in the integrand when \(D/d \ll 1\). In the limit \(D/d \gg 1\) does not make sense. In the limit \(D/d \ll 1\), to the leading order, the Casimir-Polder force is
given by
\[
\kappa(d,T, Z^{(1)}, r(0)) = -(3k_B T \Delta(\varepsilon^{(1)}, Z^{(1)}, r(0))) / (4d^4), \\
\Delta(\varepsilon^{(1)}, Z^{(1)}, r(0)) = \left( \eta_0(0) \varepsilon^{(1)} \right) \left( 1 - \frac{r(0)}{\varepsilon^{(1)} Z^{(1)}} \right) \\
\times \left( \frac{1}{1 - \varepsilon^{(1)} Z^{(1)}} \right) \\
(16)
\]

This is the Casimir-Polder force in the relatively large-separation limit. For dielectric film with no magnetic properties, the Casimir-Polder free energy and force are obtained from expressions for \( F(d,T) \) and \( \kappa(d,T) \), respectively, by putting \( \mu_0^{(1)} = 1 \). This force is generally attractive. The attractive nature in the large-separation limit is expected as the force has deep connection with the van Waals force.

We use an alternative definition of the exponential function, viz. 
\[
e^z = \lim_{n \to \infty} \left( 1 + \frac{z}{n} \right)^n
\]
where the convergence is uniform in \( |z| < R < \infty \) for every \( R \), to expand \( e^{-\kappa d/d} \) in (11). The uniform convergence implies that the term-by-term integration in the expansion is possible. In view of this and Eq. (15), the Casimir-Polder free energy assumes the simple form
\[
F(d,\ldots,T) = \sum_{\alpha \beta} \phi_{\alpha \beta} (\varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \frac{r(0)}{d}) \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \left( \frac{r(0)}{d} \right)^n
\]

where the summand is
\[
\phi_{\alpha \beta} (\varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \frac{r(0)}{d}) = \frac{\eta_0(0) \varepsilon^{(1)}}{\eta_e(0) \varepsilon^{(1)} - 1} \left( \varepsilon^{(1)} Z^{(1)} \right) \left( 1 - \frac{r(0)}{\varepsilon^{(1)} Z^{(1)}} \right) \\
\left( 1 - \frac{1}{\eta_e(0) \varepsilon^{(1)}} \right) \\
(17)
\]

We are putting in place all the relevant results with the aim to show that the repulsive forces arise in magnetic materials with non-trivial response functions [21,22]. As it has already been mentioned that they also arise for fluid-separated geometries [4], magneto-electric materials [5, 23], and the TRS broken materials [10,11,12,13].

The Casimir-Polder free energy \( F(d,T, Z^{(1)}, \ldots) \) could also be written as \( F(d,T, Z^{(1)}, \ldots) = -(3k_B T / (8d^4)) f(d, Z^{(1)}, \eta_m(0), \ldots) \)

where
\[
f(d, \varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \ldots) = \sum_{\alpha \beta} \phi_{\alpha \beta} (\varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \ldots) \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \left( \frac{r(0)}{d} \right)^n
\]

\[
(18)
\]

and a little algebra, eventually yield \( f(d,T, Z^{(1)}, \eta_m(0), \ldots) = -(3k_B T / (8d^4)) f(d, Z^{(1)}, \eta_m(0), \ldots) \), where
\[
f(d, Z^{(1)}, \eta_m(0), \ldots) = \sum_{n,m=0}^{\infty} \frac{(-1)^{m-n}}{n! m!} \sum_{\alpha \beta} \phi_{\alpha \beta} (\varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \ldots) \left( \frac{r(0)}{d} \right)^m \left( \frac{Z^{(1)}}{d} \right)^n
\]

\[
(19)
\]

It may be noted that the contributions to in, say, (19) arises from the exponential terms and not from So, the term-by-term integrations are not very cumbersome. Eq.(19) immediately yields the Casimir-Polder force as
\[
\kappa(d,T, Z^{(1)}, r(0)) = -(3k_B T / 8d^4) g(d, \varepsilon^{(1)}, Z^{(1)}, r(0)) = -(3k_B T / 8d^4) g(d, \varepsilon^{(1)}, Z^{(1)}, r(0))
\]

\[
(20)
\]

Upon expanding (20), a little rearrangement of terms enables us to write
\[
g(d, \varepsilon^{(1)}, Z^{(1)}, r(0)) = -24\eta_0(0) \left( \frac{r(0)}{d} \right) \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \left( \frac{r(0)}{d} \right)^n \left( \frac{Z^{(1)}}{d} \right)^n
\]

\[
= -120\eta_0(0) \left( \frac{r(0)}{d} \right) \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \left( \frac{r(0)}{d} \right)^n \left( \frac{Z^{(1)}}{d} \right)^n
\]

\[
(21a)
\]

where \( r(0) = \sqrt{\eta_e(0) / \eta_m(0)} \).

We are putting in place all the relevant results with the aim to show that the repulsive forces arise in magnetic materials with non-trivial response functions [21,22]. As it has already been mentioned that they also arise for fluid-separated geometries [4], magneto-electric materials [5, 23], and the TRS broken materials [10,11,12,13].

The Casimir-Polder free energy \( F(d,T, Z^{(1)}, \ldots) \) could also be written as \( F(d,T, Z^{(1)}, \ldots) = -(3k_B T / (8d^4)) f(d, Z^{(1)}, \eta_m(0), \ldots) \), where
\[
f(d, \varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \ldots) = \sum_{\alpha \beta} \phi_{\alpha \beta} (\varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \ldots) \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \left( \frac{r(0)}{d} \right)^n
\]

\[
(18)
\]

and a little algebra, eventually yield \( f(d,T, Z^{(1)}, \eta_m(0), \ldots) = -(3k_B T / (8d^4)) f(d, Z^{(1)}, \eta_m(0), \ldots) \), where
\[
f(d, Z^{(1)}, \eta_m(0), \ldots) = \sum_{n,m=0}^{\infty} \frac{(-1)^{m-n}}{n! m!} \sum_{\alpha \beta} \phi_{\alpha \beta} (\varepsilon^{(1)}, Z^{(1)}, \eta_m(0), \ldots) \left( \frac{r(0)}{d} \right)^m \left( \frac{Z^{(1)}}{d} \right)^n
\]

\[
(19)
\]
semi-phenomeological approach with the Stoner-like criterion enshrined in (23) for the attraction-repulsion crossover, will generate interest among the Casimir Physics community to cast a fresh look to the problem. We shall now investigate the Casimir-Polder interaction in the high-temperature limit. We shall also take the Matsubara frequency $\omega_l = \frac{2\pi k_BT}{\hbar}$ dependence in an approximate manner at a comparatively lower temperature.

In the high temperature (or, the large separation) regime, the long time behavior of the ubiquitous dissipation is dominated by an exponential decay with a time constant given by the first Matsubara frequency $\omega_1 = \frac{2\pi k_BT}{\hbar}$. At a given temperature $T$, for the micro-particle-sheet system, it is then desirable that $\omega_1$ for the large separation limit and not much higher, for comparatively moderate separations. This simply implies that $T >> T_c \frac{\hbar c}{(2\pi dk_B)}$ and $T \geq T_c$, respectively, for the former and the latter cases. The important outcome, unlike the Faraday-Maxwell (static) limit, is that in the high-temperature limit $k^{\omega_i}(i\omega_l, k) = k^0(i\omega_l, 0) = [e^{\omega_l(i\omega_0)} mc^2/a^2]^{1/2} = (e^{\omega_l(0)} mc^2/a^2)^{1/2}(\omega/c)$, for the comparatively moderate temperatures $k^{\omega_i}(i\omega_l, k) = (e^{\omega_l(0)} mc^2/a^2)^{1/2}(\omega/c) [1 + (k^2/2)e^{\omega_l(0)} mc^2/a^2(\omega/c)^2]$. (24)

It is easy to see that, for the former case, the criterion for the attractive Casimir-Polder interaction to turn repulsive is formally given by Eq. (23). Only the quantities, such as $\mathcal{Z}_m^{(i\omega_l, T_i)}$, are not defined anymore by Eq. (22). These are rather given by $\mathcal{Z}_m^{(i\omega_l, T_i)}(c^{(i\omega_l, T)^2})$ and $\mathcal{Z}_m^{(i\omega_l, T_i)}(c^{(i\omega_l, T)^2})$; have been put to one above. The superscript ‘HT’ stands for the high-temperature limit. Strictly speaking, we shall have to consider the frequency ($\omega$) dependences of the permeability ($\mu$) and the permitivity ($\varepsilon$) of the sheet material as well, for all information about the optical properties of the surface is encoded in these response functions. In the final leg of this article, we shall take up this issue. We emphasize that, as long as the frequency dependence of the response functions are ignored, the crucial result, when the frequency dependence is completely ignored, given by Eq. (23) is not formally different from the high-temperature limit result.

For the not-so-high temperatures case, we shall have

$$\mathcal{Z}_m^{(i\omega_l, T_i)}(c^{(i\omega_l, T)^2}) = \left[ \mathcal{Z}_m^{(i\omega_l, T_i)}(c^{(i\omega_l, 0)^2}) - \frac{\epsilon_0^2}{2\alpha_0^2} \right] - \frac{\epsilon_0^2}{2\alpha_0^2} \left[ \frac{\epsilon_0^2}{2\alpha_0^2} + \frac{1}{\alpha_0^2} \right],$$

$$\alpha_0^2(T) = n^{(2)} = \epsilon_0^{(2)}\mu_0^{(2)} = \epsilon_0^{(2)}Z_0^{(2)}.$$

The temperature lowering can lead to a complete cancellation or the change of sign of the micro-particle–sheet interaction. We note that now the contributions to $k$-integration in, say, Eq.(17) arise from the exponential term $e^{-\kappa D/d}$, as well as from $\mathcal{Z}_m^{(i\omega_l, T_i)}(c^{(i\omega_l, T)^2})$. So, the term-by-term integrations and overall calculations will be a little more cumbersome. We wish to continue below together with the expansions, of $(\mathcal{Z}_e, \mathcal{Z}_m)$ in (25) and (26), under the moderately high temperature assumption reflected in the inequality $\kappa^2/(\alpha_0 T) << 1$. The problem is tractable under this assumption. The expansions are

$$\mathcal{Z}_e^{(i\omega_l, T_i)}(c^{(i\omega_l, T)^2}) = \left[ \mathcal{Z}_e^{(i\omega_l, T_i)}(c^{(i\omega_l, 0)^2}) - \frac{\epsilon_0^2}{2\alpha_0^2} \right] - \frac{\epsilon_0^2}{2\alpha_0^2} \left[ \frac{\epsilon_0^2}{2\alpha_0^2} + \frac{1}{\alpha_0^2} \right],$$

$$\alpha_0^2(T) = n^{(2)} = \epsilon_0^{(2)}\mu_0^{(2)} = \epsilon_0^{(2)}Z_0^{(2)}.$$

where

$$\mathcal{Z}_m^{(i\omega_l, T)^2} = \left[ \mathcal{Z}_m^{(i\omega_l, T)^2} - \frac{\epsilon_0^2}{2\alpha_0^2} \right] - \frac{\epsilon_0^2}{2\alpha_0^2} \left[ \frac{\epsilon_0^2}{2\alpha_0^2} + \frac{1}{\alpha_0^2} \right],$$

using Eqs. (28)-(31), we find that for the comparatively moderate temperatures, the formal free energy expression could be written as

$$F(d(T_i), c^{(i\omega_l, T)^2}, \mu^{(i\omega_l, T)^2}, \eta_0(0), \eta_m(0)) = -$$

$$\sum_{\alpha_0^2} \int_0^T \mathcal{Z}_m^{(i\omega_l, T)^2} d\omega_0^2 e^{-\kappa^2 d/T} =$$

$$\sum_{\alpha_0^2} \int_0^T \mathcal{Z}_m^{(i\omega_l, T)^2} d\omega_0^2 e^{-\kappa^2 d/T} =$$

$$\sum_{\alpha_0^2} \int_0^T \mathcal{Z}_m^{(i\omega_l, T)^2} d\omega_0^2 e^{-\kappa^2 d/T} =$$

We have used (17),(28)-(31) in Eq. (33). In the expansion in (33)
we do not consider the terms of O(order higher than what we have shown. The various terms in (33) are given by

\[
I_{p}^{\text{HTI}} = \frac{e^{\frac{\text{KD}}{\alpha}}}{(1 - e^{-\frac{\text{KD}}{\alpha}})} \left( \frac{d_{p}^{2}}{\text{K}^{2}} \right) + \frac{e^{\frac{\text{KD}}{\alpha}}}{(1 - e^{-\frac{\text{KD}}{\alpha}})} \left( \frac{\text{K}^{2}}{d_{p}^{2}} \right)
\]

\[
C_{p} = \left( \frac{\text{K}^{2}}{d_{p}^{2}} \right) \left( \frac{e^{\frac{\text{KD}}{\alpha}}}{(1 - e^{-\frac{\text{KD}}{\alpha}})} \right)
\]

(34)

With \( |c_{p}|, |d_{p}| \ll 1\), one may approximate the second term in (33) as

\[
-\sum_{n=1}^{\infty} \eta_{n}(0) A_{\text{HTI}} (\omega_{l} T) \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) \chi_{\omega_{l}}^{(1)} \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) + O\left( \left( \frac{e^{i \omega_{l} T}}{2 \pi \omega_{l} T} \right)^{2} \right)
\]

(35)

Upon integration, the term within parentheses yields 120 \( [1 + 3(2 \pi \omega_{l} T)^{2}] \).

Since we are not considering the low temperature limit, we may replace \( \omega_{l} \) by \( \omega_{l} = 2 \pi k_{B} T / \hbar \) in the integral \( f \). We then have

\[
\sim \sum_{n=1}^{\infty} \frac{d_{n}^{2}}{\text{K}^{2}} \left( \frac{e^{i \omega_{l} T}}{(2 \pi \omega_{l} T)} \right) \chi_{\omega_{l}}^{(1)} \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) + O\left( \left( \frac{e^{i \omega_{l} T}}{2 \pi \omega_{l} T} \right)^{2} \right)
\]

(36)

\[
\sum_{n=1}^{\infty} \frac{d_{n}^{2}}{\text{K}^{2}} \left( \frac{e^{i \omega_{l} T}}{(2 \pi \omega_{l} T)} \right) \chi_{\omega_{l}}^{(1)} \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) = 0
\]

The first term in the series (33) above is

\[
\sum_{n=1}^{\infty} \frac{d_{n}^{2}}{\text{K}^{2}} \left( \frac{e^{i \omega_{l} T}}{(2 \pi \omega_{l} T)} \right) \chi_{\omega_{l}}^{(1)} \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) \approx 0
\]

This is given by Eq.(18) albeit with a slight difference in the definition of \( \left( \frac{\text{K}^{2}}{d_{p}^{2}} \right) \). The functions \( \left( \frac{\text{K}^{2}}{d_{p}^{2}} \right) \) are now given by (36) and (37). The second term in the series (33) above is given by (35). Thus the function \( f(.,d,T, \epsilon_{(1)} , \ldots) \) is given by

\[
f(.,d,T, \epsilon_{(1)} , \ldots) = \sum_{n=1}^{\infty} \frac{d_{n}^{2}}{\text{K}^{2}} \left( \frac{e^{i \omega_{l} T}}{(2 \pi \omega_{l} T)} \right) \chi_{\omega_{l}}^{(1)} \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) + O\left( \left( \frac{e^{i \omega_{l} T}}{2 \pi \omega_{l} T} \right)^{2} \right)
\]

(37)

The significant difference between (19) and (38) is as follows: While all the coefficients in (19) are temperature independent, obvious from (38) that, though the coefficients of \( (D/d_{m})^{m} \) \( (m=0,1,2) \) will be temperature independent, the remaining ones will be temperature dependent due to the function \( A_{\text{HTI}} (\omega_{l} T) \). Owing to the presence of the last term in Eq.(38), it is not difficult to see that the correction to \( g(d, \epsilon_{(1)}, \ldots, r(0)) \) in Eq.(20), involving the same function, is

\[
\Delta_{\text{HTI}} (\omega_{l} T, \epsilon_{(1)}, \ldots, r(0)) = 360 \sum_{n=1}^{\infty} \frac{d_{n}^{2}}{\text{K}^{2}} \left( \frac{e^{i \omega_{l} T}}{(2 \pi \omega_{l} T)} \right) \chi_{\omega_{l}}^{(1)} \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) + O\left( \left( \frac{e^{i \omega_{l} T}}{2 \pi \omega_{l} T} \right)^{2} \right)
\]

(39)

With this correction, as in (23), we immediately find that as long as we have

\[
\frac{\left( \frac{r(0)}{r(0)} \right)}{\left( \frac{r(0)}{r(0)} \right)} \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right)
\]

(40)

the force is attractive. When

\[
\frac{\left( \frac{r(0)}{r(0)} \right)}{\left( \frac{r(0)}{r(0)} \right)} \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right) \left( \frac{\epsilon_{(1)}}{\epsilon_{(1)}} \right)
\]

(41)

the force turns repulsive. Inequations (40) and (41) reduce to (23), as they should, when \( ((2D \omega_{l} c)^{-2} << 1 \) (high-temperature limit). Here

\[
\sum_{n=1}^{\infty} \frac{d_{n}^{2}}{\text{K}^{2}} \left( \frac{e^{i \omega_{l} T}}{(2 \pi \omega_{l} T)} \right) \chi_{\omega_{l}}^{(1)} \left( \frac{(e^{i \omega_{l} T})^{2}}{(2 \pi \omega_{l} T)} \right) = 0
\]

(42)

We notice that the Casimir-Polder(CP) force not only arises from the reflection coefficients of the electromagnetic fluctuations on the sheet material plus substrate, there is also thermal contribution [1,18]. The contribution is through the dependence on the Matsubara frequencies.

We shall do some graphics now to see what does inequation (23) convey. Analyzing the high temperature and the moderate temperature conterparts of (23) one may not gain probably a very different insight compared to what could be obtained from it. Therefore, the analysis of these results are not in the agenda at
the moment. The term within the parenthesis in the right-hand-side of (21a) is \( F(d, \varepsilon^{(1)}, Z^{(1)}, r(0)) = \frac{pD}{(D/d)} \), \( (D/d) \int (D/d) \).

Upon expanding up to the fifth order, we find that \( F(d, \varepsilon^{(1)}, Z^{(1)}, r(0)) \) is a quintic in \( (D/d)\):

\[
F(d, \varepsilon^{(1)}, Z^{(1)}, r(0), \omega = 0) = -21p + 260.4 \left( \frac{p}{d} \right)^2 + (14p + 84) \left( \frac{p}{d} \right)^4 - (0.75p + 24.5) \left( \frac{p}{d} \right)^3 + (5p + 6) \left( \frac{p}{d} \right)^2 - (2.5p + 1) \left( \frac{p}{d} \right) + p
\]

Thus, the criterion (23) could now be expressed as if \( F(d, \varepsilon^{(1)}, Z^{(1)}, r(0)) \) is greater (less) than zero, the Casimir-Polder interaction is attractive(repulsive). To set the tone and the tenor of the discussion, we investigate the situation first with the aid of Eq.(16). We suppose that the film materials have access to non-trivial permeability and permittivity. The force could then be repulsive as well as we see below. We have plotted \( \mathcal{D}(\varepsilon^{(1)}, Z^{(1)}, r(0)) \) as a function of \( Z^{(1)} \) for \( \varepsilon^{(1)} = 14 \), and \( r(0) = 0.20 \) (curve1), 0.30 (curve2), 0.40 (curve3), and 0.50 (curve4) in Figure 2 (In Figure 2, \( r(0) \) has been indicated by \( Z_r \)). The curves are recliner-shaped. The bend of the recliners, where \( K(d, T, Z^{(1)}, r(0)) = -3k_B T/4D^4 \) (\( D/d \)), shifts towards left as \( r(0) \) decreases. We find that the force is generally attractive except at near-extreme values of \( Z^{(1)} \) (0.05) and the polarizability ratio \( r(0) \) (0.40 -0.50). The values indicate that, if the micro-particle has higher polarizability ratio compared to the magnetic response and the electric response ratio of the sheet, the repulsion is accessible.

![Figure 2: A plot of Casimir-Polder force \( \mathcal{D}(\varepsilon^{(1)}, Z^{(1)}, r(0)) \) as a function of \( Z^{(1)} \) for \( \varepsilon^{(1)} = 14 \), and \( r(0) = 0.20 \) (curve1), 0.30 (curve2), 0.40 (curve3), and 0.50 (curve4) in the relatively large-separation limit. The force is generally attractive except at non-trivial values of \( Z^{(1)} \) (0.05) and \( r(0) \) (0.40 -0.50).

For the 2D graphics, we have assumed \( \varepsilon^{(1)} = 14 \), \( Z^{(1)} = 0.5 \) and 1.00, and \( r(0) = 0.20 \) (curve1), 0.30 (curve2), 0.40 (curve3), and 0.50 (curve4) in the relatively large-separation limit. The force is generally attractive except at non-trivial values of \( Z^{(1)} \) (0.05) and \( r(0) \) (0.40 -0.50).

\[
\mathcal{D}(\varepsilon^{(1)}, Z^{(1)}, r(0)) = \sqrt{\eta_m(0)/\eta_e(0)} = (01, 02, 03, 04). \text{ With } (\varepsilon^{(0)}, \mu^{(0)}, \varepsilon^{(2)}, \mu^{(2)}, \eta^{(0)}) = 1, \text{ we depict the crucial part of the Casimir-Polder interaction, viz. the function } F(d, \varepsilon^{(1)}, Z^{(1)}, r(0), \omega = 0) \text{ in the static limit. We have approximated it by a quintic in } (D/d).
\]

In figure 3(a) \( (\varepsilon^{(1)} = 14, \varepsilon^{(1)} = 0.5 \) and \( r(0) = (01, 02, 03, 04) \) ), we find that interaction is attractive as long as \( (D/d) \geq 0.2, \text{ or, } d \geq 5 \text{ D. For } (D/d) > 0.2 \text{ (or, } d < 5 \text{ D), the interaction is repulsive, while in figure 3(b) } (\varepsilon^{(1)} = 0.4, \varepsilon^{(1)} = 1.00, \text{ and } r(0) = (01, 02, 03, 04) \), we find that interaction is attractive as long as \( (D/d) \geq 0.1, \text{ or, } d \geq 10 \text{ D. For } (D/d) > 0.1 \text{ (or, } d < 10 \text{ D), the interaction is repulsive. The results (repulsion at smaller separation } (d/D) \text{ ~1} \text{ and the attraction at larger separation } (d/D) \text{ ~10} \text{ are expected as the Casimir-Polder/Casimir forces are very closely linked with the van der Waals force. Additionally, we notice that, for the repulsion purpose, the sheet material is relatively high in the magnetic response (and the micro-particle has low magnetic polarizability). Generally, it is known [24,25] that for this purpose one requires a magnetic response strong enough to dominate the electric response of the material in a broad range of frequencies. Since this stringent condition is not met by any natural material, there has been a quest for an artificial material whose properties could be tailored in this direction.}

As regards the 3D graphics, we have taken non-trivial values of the parameters. The sheet used for obtaining Figure 4 may be termed as a moderate dielectric = 14, for obtaining Figure 5 as a poor dielectric \( (\varepsilon^{(1)} = 1.25) \), and for Figure 6 as a good dielectric \( (\varepsilon^{(1)} = 36.8) \). The polarizability ratio \( r(0) = \sqrt{\eta_m(0)/\eta_e(0)} \) is 20.00. A’spot of vulnerability’ appears at \( Z^{(1)} < 1 \) for \( d > 4 \text{ D} \), and \( Z^{(1)} = 1.00, \text{ and } r(0) = (01, 02, 03, 04) \). With \( (\varepsilon^{(0)}, \mu^{(0)}), (\varepsilon^{(2)}, \mu^{(2)}), (\eta^{(0)}) = 1, \text{ we depict the quintic, } F < 0 \text{ (repulsive). At } Z^{(1)} = 1.5 \text{ a sudden increase in the magnitude of } F \text{ occurs. In Figure 7(b), on the other hand, with the dielectric function value } \varepsilon^{(1)} = 25.26 \text{ (good dielectric), and } (D/d) = 0.10 \text{ or } d = 10 \text{ D (i.e, the meta-material sheet and the micro-particle separation } d > D \text{) } \), \text{ we find that the quintic, } F < 0 \text{ (repulsive). At } Z^{(1)} = 0.5 \text{ a sudden change in } F \text{ occurs; it becomes positive(attractive). The numbers above are artefacts of the approximation made. The facts enlisted, however, indicate that the tale of metamaterials have some ingredients where the strange and bizarre is blurred beyond clarity.}

On a quick side note, the frequency (\( \omega \)) and the permittivity (\( \varepsilon \)) and the permittivity (\( \varepsilon \)) of the sheet material must be taken into consideration, for all information about the optical properties of the surface is encoded in these response functions. We may consider the possibility of the sheet material as a metal. The metals are good conductors but not good dielectrics; the non-local effects are not important for the metal. At optical frequencies (\( \omega \sim 10^{16} \text{Hz} \)), the metallic conductivity is \( \sigma \sim 10^{2} \Omega^{-1} \text{m}^{-1}, \varepsilon(\omega) \sim \varepsilon_{0} \sim 10^{-11} \text{SI unit, and } \mu \sim \mu_{0} \sim 10^{-6} \text{SI unit. These ensure that } (\omega \varepsilon(\omega)/\sigma) \ll 1 \text{ typically valid for all metals. As the interaction between the surface plasmon resonances contribute to the Casimir energy, one may adopt the lossy Drude model expression [26] for the permittivity of metal: } \varepsilon(\omega)/\varepsilon_{0} = [1 - \omega^{2}/(\omega^{2} + i\gamma \omega)]. \text{ In Figure 7(b), one finds that the imaginary part of } \varepsilon(\omega) \text{ appears as a delta function. The calculation of the Casimir force requires response functions at imaginary frequencies. We use the Kramers-Kronig relation: } \varepsilon(\omega)/\varepsilon_{0} = [1 + (2/\pi) \int_{\omega}^{\infty} \text{Im} \varepsilon(\omega)/\omega^{2}]. \text{ The relation}

\[ \varepsilon(i\omega l)/\varepsilon_0 = \left[1 + \left(\frac{2}{\pi}\right) \left(\frac{\omega_p^2}{\omega_l^2}\right)\right] \]

Here, \( \omega_l = (2\pi lk BT/\hbar) \) are (imaginary) Matsubara frequencies. The non-local effects are, however, important for the poor conductors. The permittivity expression \([26]\) of such materials is given by
\[ \varepsilon(i\omega l, k)/\varepsilon_0 = 1 + \left(\frac{\alpha \omega_p^2}{\omega_l^2} (vk \omega_l)\right) \]
with focus on the case with constant \( \kappa \to 0 \). The response function \( \mu(\omega) \) at imaginary frequencies is given by the Kramers-Kronig relation. We find
\[ \mu(i\omega) / \mu_0 = 1 + \left(\frac{\omega_p^2}{\omega_m^2}\right) \]
where the magnetic counterpart of the plasma frequency is \( \omega_m = \omega_p \sqrt{f} \). Our analysis above have already indicated that for accessing the CP repulsion one needs to have the overwhelming magnetic response in the material under consideration compared to the electric response. In order to give Eq.(23) – the key result gives
\[ \varepsilon(i\omega)/\varepsilon_0 = \left[1 + \left(\frac{2}{\pi}\right) \left(\frac{\omega_p^2}{\omega_l^2}\right)\right] \]
of the paper – a comprehensive look, it is therefore necessary to include the frequency dependences of $\mu$ and $\varepsilon$ in the theory.

We have developed here a semi-phenomenological approach for the CP repulsion problem and obtained a Stoner-like criterion given by Eq.(23) for the attraction-repulsion crossover, notwithstanding the fact that the comprehensive investigation of the present problem requires dealing with a quantum-mechanical description. The graphical representations reveal that a strong magnetic response must dominate over the electric response of the material under investigation in a broad range of frequencies for the CP repulsion to become a reality. The prediction regarding artificial materials, such as the meta-materials [24,25] (MM) and the chiral meta-materials [27,28] (CMM), with tunable magneto-dielectric properties fuelled the hope of realizing the Casimir/CP repulsion and nano-levitation effect on demand in the second half of the last decade. The quest for the exotic material capable to deliver the Casimir/CP repulsion appeared to have been met with initial success. The existence of a repulsive Casimir force was found to depend upon the strength of the chirality($\sigma$) [27,28]. It must be mentioned that the MMs are basically made of nanostructures carefully fabricated to access a particular electromagnetic feature. For instance, the simultaneous occurrence of the negative values for the permittivity and the permeability is the requirement that yields a ‘left-handed’ medium in which light propagates with opposite phase and energy velocities—a condition described by a negative refractive index in the electromagnetic domain. The CMMs, on the other hand, are separate class of MMs where the refractive index $n = \sqrt{\mu \sigma} = 1$ where $\sigma 0$. The hope, however, was dashed as the very conjecture of accessing the repulsive Casimir effect based on the CMMs was adjudged to be doubtful [29]. The reason shown by the authors [29] is that the proposal is irreconcilable with the causality and the passivity of the material, to tune up the condition for the attraction-repulsion crossover.
